Correlated features

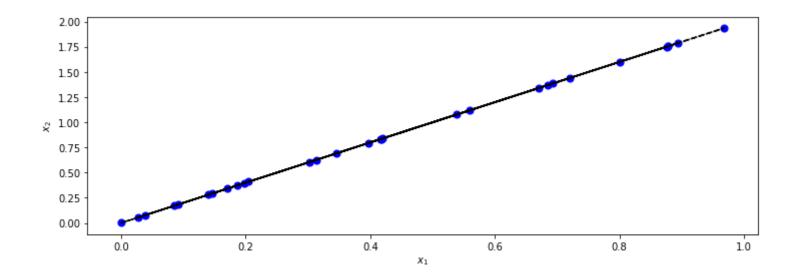

Consider the following set of examples with 2 features

```
In [4]: import numpy as np
import matplotlib.pyplot as plt

%matplotlib inline

m = 30
    rng = np.random.RandomState(1)
    x_1 = rng.rand(m)
    x_2 = 2 * x_1

fig, ax = plt.subplots(1,1,figsize=(12,4))
    _= ax.scatter( x_1, x_2, color="blue", s=50)
    _= ax.plot( x_1, x_2, color="blue", linestyle="dashed")
    _= ax.set_xlabel("$x_1$")
    = ax.set_ylabel("$x_2$")
```

As you can see

- \boldsymbol{x}_2 is perfectly correlated with \boldsymbol{x}_1

$$\mathbf{x}_2^{(\mathbf{i})} = 2*\mathbf{x}_1^{(\mathbf{i})}$$

A way to conceptualize $\mathbf{x^{(i)}}$

• As a point in the space spanned by unit basis vectors

$${f u}_{(1)}=(1,0)$$

$$\mathbf{u}_{(2)}=(0,1)$$

ullet With $\mathbf{x^{(i)}}$ having exposure

$$\mathbf{x}_1^{(\mathbf{i})}$$
 to $\mathbf{u}_{(1)}$

$$\mathbf{x}_2^{(\mathbf{i})}$$
 to $\mathbf{u}_{(2)}$

So example $\mathbf{x^{(i)}}$ is

$$\mathbf{x^{(i)}} = \sum_{j'=1}^2 \mathbf{x}_{j'}^{(i)} * \mathbf{u}_{(j')}$$

But because

$$\mathbf{x}_2^{\mathbf{(i)}} = 2*\mathbf{x}_1^{\mathbf{(i)}}$$

we can create an alternate basis vector

$$ilde{\mathbf{v}}_{(1)}=(1,2)$$

such that example $\mathbf{x^{(i)}}$ is

$$\mathbf{x^{(i)}} = ilde{\mathbf{x}}_1^{(i)} * ilde{\mathbf{v}}_{(1)}$$

where $ilde{\mathbf{x}}_1^{(\mathbf{i})} = \mathbf{x}_1^{(\mathbf{i})}$

That is, $\mathbf{x^{(i)}}$ has exposure $\tilde{\mathbf{x}}_1^{(i)}$ to the new, single basis vector.

So

- Rather than representing $\mathbf{x^{(i)}}$ as a vector with 2 features (in the original basis)
- We can represent it as $\tilde{\mathbf{x}}^{(i)}$, a vector with 1 feature (in the new basis)

This is the essence of dimensionality reduction

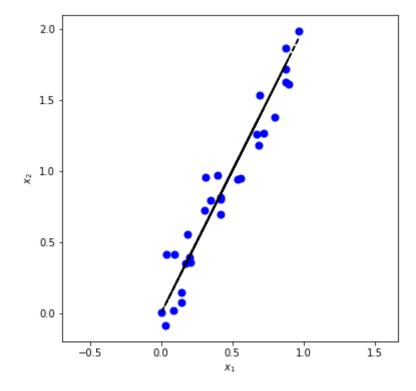

Changing bases to one with fewer basis vectors

```
In [5]: eps = .01
    x_2p = 2 * x_1 + .2 * rng.randn( x_1.shape[0] )

    x_p = np.concatenate( [ x_1.reshape(-1,1), x_2p.reshape(-1,1)], axis=1)

    fig, ax = plt.subplots(1,1,figsize=(6,6))
    _= ax.scatter( x_p[:,0], x_p[:,1], color="blue", s=50)
    _= ax.plot( x_1, x_2, color="black", linestyle="dashed")
    _= ax.set_xlabel("$x_1$")
    _= ax.set_ylabel("$x_2$")
    _= ax.axis("equal")
```

In this case

- A second basis vector $\tilde{\mathbf{v}}_{(2)}$
- Orthogonal to the first

$$ilde{\mathbf{v}}_{(1)}\cdot ilde{\mathbf{v}}_{(2)}=0$$

could approximate $\mathbf{x}^{(i)}$

$$\mathbf{x^{(i)}} = \sum_{j'=1}^2 ilde{\mathbf{x}}_{j'}^{(i)} * ilde{\mathbf{v}}_{(j')}$$

```
In [6]: | from sklearn.decomposition import PCA
        import math
        pca x2p = PCA()
        \#x p = x p - x p.mean(axis=0)
        pca x2p proj = pca x2p.fit transform(x p)
        def draw vector(v0, v1, ax=None):
            arrowprops=dict(arrowstyle='->',
                            linewidth=2,
                            color="black",
                             shrinkA=0, shrinkB=0)
            = ax.annotate('', v1, v0, arrowprops=arrowprops)
            return ax
        fig, ax = plt.subplots(1,1, figsize=(6,6))
        mean = x p.mean(axis=0)
        maxp = np.sqrt(pca x2p.explained variance [-1])
        = ax.scatter(x p[:,0], x p[:,1], color="blue", s=10)
        for i in range(0, 2):
            comp, length = pca x2p.components [i], pca x2p.explained variance [i]
            v = comp # * np.sqrt(length)
            = draw vector( mean, mean + v , ax=ax)
        = ax.scatter( mean[0], mean[1], s=50, color="black")
        = ax.axis("equal")
```

The black lines represent the alternate basis vectors $\tilde{\mathbf{v}}_{(1)}, \tilde{\mathbf{v}}_{(2)}.$

As you can see:

- The variation along $ilde{\mathbf{v}}_{(1)}$ is much greater than that around $ilde{\mathbf{v}}_{(2)}$
- Capturing the notion that the "main" relationship is along $\tilde{\mathbf{u}}_{(1)}$

In fact, if we dropped $ilde{\mathbf{v}}_{(2)}$ such that $|| ilde{\mathbf{x}}||=1$

- ullet The examples would be projected onto $ilde{\mathbf{v}}_{(1)}$
- With little information being lost

Subsets of correlated features

It may not be the case that a group of features is correlated across all examples

Consider the MNIST digits

- The subset of examples corresponding to the digit "1"
- Have a particular set of correlated features (forming a vertical column of pixels)
- Which may not be correlated with the same features in examples corresponding to other digits

Thus, a synthetic feature encodes a "concept" that occurs in many but not all examples

The "concept" will be discovered

- It may not necessarily be the pattern of features that corresponds to an entire digit
- It may be a partial pattern common to several digits
 - Vertical band (0, 1, 4, 7)
 - Horizontal band at top (5, 7, 9)

```
In [7]: print("Done")
```

Done
